SIMD ALGORITHMS FOR D ARRAYS IN SHUFFLE NETWORKS (CLASSIC REPRINT) (PAPERBACK)

Forgotten Books, United States, 2015. Paperback. Book Condition: New. 229 x 152 mm. Language: English . Brand New Book ***** Print on Demand *****.Excerpt from Simd Algorithms for D Arrays in Shuffle Networks 1. Introduction and the Model Schwartz [1] introduced the idea of a parallel processor based on the shuffle connections (2); reviewed various bank of SIMD algorithms for such an ensemble of processors, and analyzed their asymptotic time complexities. However, these algorithms are designed for the 1-D case, where N , the size of the problem is restricted to be P , the number of processors. In reality, the general case where $N > P$ is much more likely to appear. In this case each processor stores $L = S/P$ data elements in its local memory. This data structure is referred to as a 2-D array of P columns and L rows, where the i th column corresponds to the local memory of the processor PE_i . Our algorithms correspond to a SIMD Perfect Shuffle connected machine (PS) [1]. For simplicity, although it is not crucial, we assume that P is a power of two. The processors are ordered left to right and are numbered $0 - P-1$ accordingly, so we denote the i th processor PE_i ; Subgroups of processors are referred to in a natural manner: left half, right half, odd, even etc. There are three kinds of communication steps: shuffle (σ), unshuffle (σ^{-1}) and exchange (X) and a processor internal (fixed-size) computation. All of these operations take one time step. In any parallel network machine we have two possible working modes: One in which each processor computes a local result of a sequential computation using its local data. Then an inter-processor global algorithm is carried out to compute the final result. In other words, this mode involves separate sequential work by PE_i ...
